

**Section 6 2 Covalent Bonding**

Most covalent molecules you will come across are formed by combinations of atoms of non-metallic elements on the right-hand side of the Periodic Table eg from Group 4 carbon and silicon, from Group 5 nitrogen and phosphorus and from the Group 7 Halogens - fluorine, chlorine, bromine and iodine.

This page explains what covalent bonding is. It starts with a simple picture of the single covalent bond, and then modifies it slightly for A'level purposes. It also goes on to a more sophisticated view involving hybridisation. This isn't required by many UK-based syllabuses at this level. However

Halogen bonding is a type of non-covalent interaction which does not involve the formation nor breaking of actual bonds, but rather is similar to the dipole-dipole interaction known as hydrogen bonding.

**Non-covalent interactions - Wikipedia**

A hydrogen bond is the attraction between the lone pair of an electronegative atom and a hydrogen atom that is bonded to either nitrogen, oxygen, or fluorine. The hydrogen bond is often described as a strong electrostatic dipole-dipole interaction.

For example, the electron number (EN) of the metal in [ML<sub>l</sub>X<sub>x</sub>Z<sub>z</sub>], i.e. the electron count, is given by  $EN = m + 2l + x$ , where m is the number of valence electrons on the neutral metal atom.

Energy Level Cross Section. Electrons are in regions around the nucleus that are different distances away from the nucleus. The electrons surround the nucleus in 3 dimensions but it is easier to show an energy level model in two dimensions like the model that looks like a target.

The repulsive energy goes up as  $(d_i / R)^{12}$ , where R is the distance between the atoms and  $d_i$  is the distance threshold below which the energy becomes repulsive.  $d_i$  depends on the types of atoms.
